

# Probing proton-neutron pairing with Gamow-Teller strengths in two- nucleon configurations

Yutaka Utsuno

*Advanced Science Research Center, Japan Atomic Energy Agency  
Center for Nuclear Study, University of Tokyo*

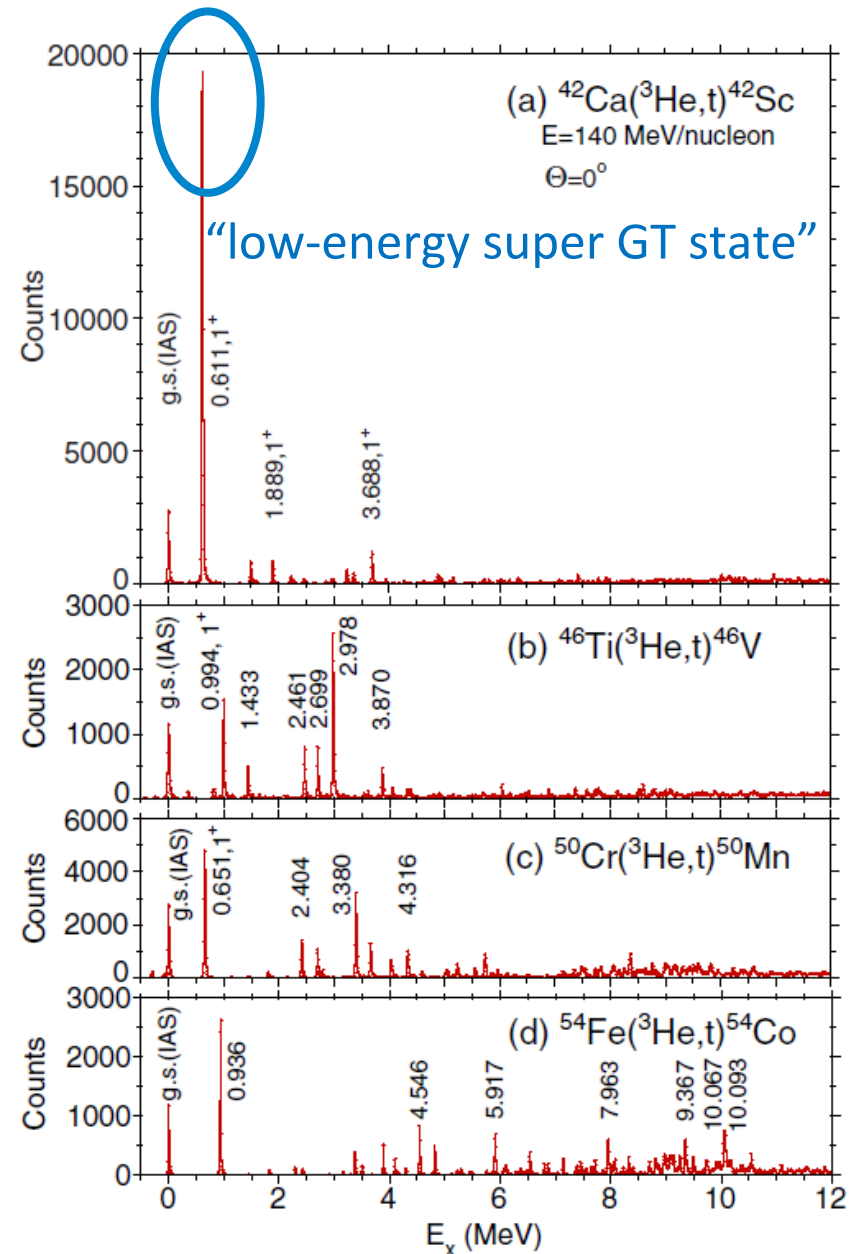

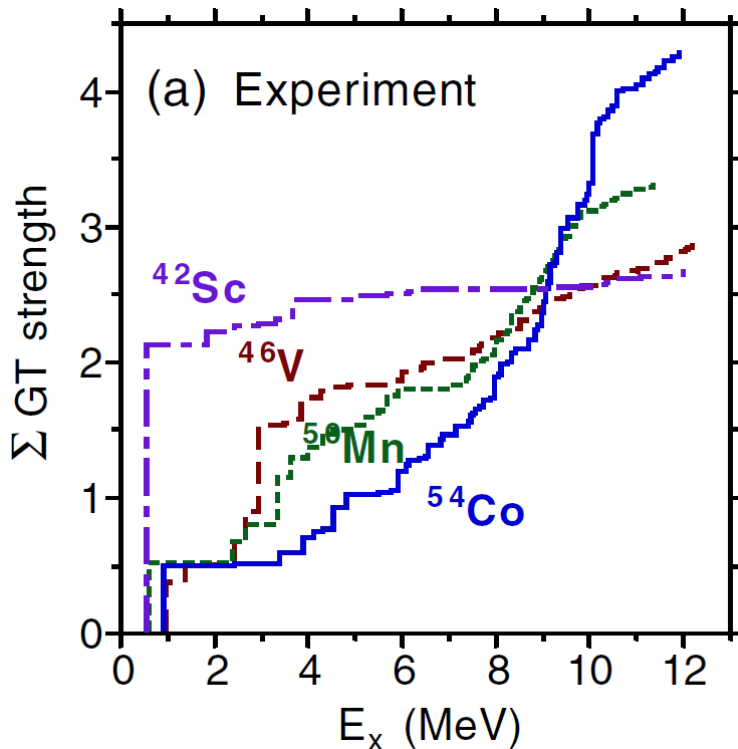

# Introduction: Fujita-san's seminar in Jan. 2016

- Systematics of Gamow-Teller distributions for  $N=Z+2 \rightarrow N=Z$  nuclei
  - Using charge exchange reaction ( ${}^3\text{He}, t$ )

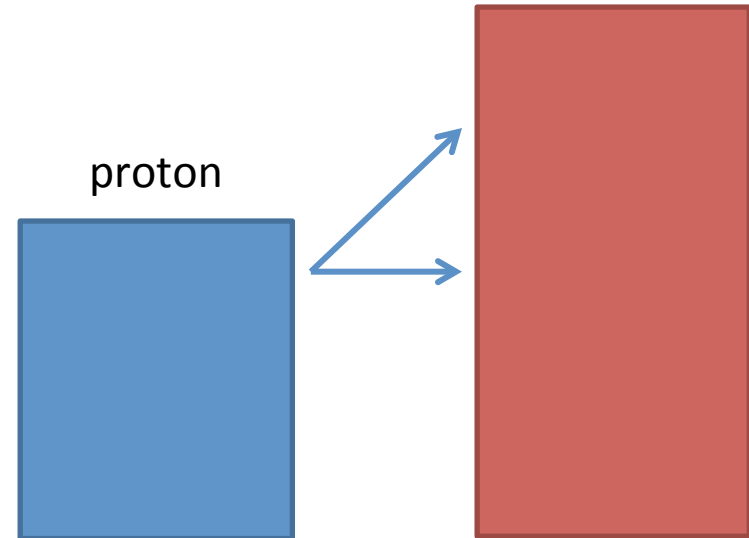

# Observed GT strength

- Concentration in the  $1^+_1$  level for  $^{42}\text{Ca} \rightarrow ^{42}\text{Sc}$ 
  - $B(\text{GT}; 0^+_1 \rightarrow 1^+_1) = 2.2$

# Ikeda sum rule

- When  $B(GT)$  is defined as  $B(GT \uparrow_{\pm}; i \rightarrow f) = |\alpha \downarrow f \uparrow \downarrow f| \sigma t \uparrow_{\pm} | \alpha \downarrow i \uparrow \downarrow i | \uparrow 2 / 2 J \downarrow i + 1 = \sum_{\mu} M \downarrow f \uparrow \downarrow \mu | \alpha \downarrow f \uparrow \downarrow f M \downarrow f \sigma \downarrow \mu t \uparrow_{\pm} \alpha \downarrow i \uparrow \downarrow i M \downarrow i | \uparrow 2$ ,  
 $\sum_{f \uparrow} B(GT \uparrow_{-}; i \rightarrow f) - \sum_{f \uparrow} B(GT \uparrow_{+}; i \rightarrow f) = 3(N - Z)$  is satisfied.  
 (with  $t \uparrow_{-} | n \rangle = | p \rangle$ )
- If GT+ transition is hindered by Pauli blocking,  $\sum_{f \uparrow} B(GT \uparrow_{-}; i \rightarrow f)$  is close to  $3(N - Z)$ .
  - $\sum_{f \uparrow} B(GT \uparrow_{-}; i \rightarrow f)$  for  $^{42}\text{Ca}$  should be close to 6, if proton excitation to the  $pf$  shell is small.

# Proof of the Ikeda sum rule

The sum of  $B(\text{GT})$  values are written as

$$\begin{aligned}
 & \sum_f B(\text{GT}^{\pm i} \rightarrow f) \\
 = & \sum_{\alpha_f J_f M_f} |\langle \alpha_f J_f M_f | \sum_k \sigma_{\mu}(k) t^{\pm}(k) | \alpha_i J_i M_i \rangle|^2 \\
 = & \sum_{\alpha_f J_f \mu M_f} \langle \alpha_i J_i M_i | \sum_{k'} (t^{\pm})^{\dagger}(k') \sigma_{\mu}^{\dagger}(k') \alpha_f J_f M_f \rangle \langle \alpha_f J_f M_f | \sum_k \sigma_{\mu}(k) t^{\pm}(k) | \alpha_i J_i M_i \rangle \\
 = & \langle \alpha_i J_i M_i | \sum_{\mu k k'} (-1)^{\mu} \sigma_{-\mu}(k') \sigma_{\mu}(k) t^{\mp}(k') t^{\pm}(k) | \alpha_i J_i M_i \rangle.
 \end{aligned} \tag{1}$$

Here we define

$$O^{\pm} = \sum_{\mu k k'} (-1)^{\mu} \sigma_{-\mu}(k') \sigma_{\mu}(k) t^{\mp}(k') t^{\pm}(k) \tag{2}$$

and get

$$\begin{aligned}
 O^{-} - O^{+} &= \sum_{\mu k k'} (-1)^{\mu} \{ \sigma_{-\mu}(k') \sigma_{\mu}(k) t^{+}(k') t^{-}(k) - \sigma_{-\mu}(k') \sigma_{\mu}(k) t^{-}(k') t^{+}(k) \} \\
 &= \sum_{\mu k k'} (-1)^{\mu} \{ \sigma_{-\mu}(k') \sigma_{\mu}(k) t^{+}(k') t^{-}(k) - \sigma_{-\mu}(k) \sigma_{\mu}(k') t^{-}(k) t^{+}(k') \} \\
 &= \sum_{\mu k k'} (-1)^{\mu} \{ \sigma_{-\mu}(k') \sigma_{\mu}(k) t^{+}(k') t^{-}(k) - \sigma_{\mu}(k) \sigma_{-\mu}(k') t^{-}(k) t^{+}(k') \} \\
 &= \sum_{\mu k} (-1)^{\mu} \sigma_{-\mu}(k) \sigma_{\mu}(k) \{ t^{+}(k) t^{-}(k) - t^{-}(k) t^{+}(k) \} \\
 &= \sum_{\mu k} 2(-1)^{\mu} \sigma_{-\mu}(k) \sigma_{\mu}(k) t_z(k) \\
 &= \sum_k 2 \{ \sigma_x^2(k) + \sigma_y^2(k) + \sigma_z^2(k) \} t_z(k) \\
 &= 6T_z.
 \end{aligned} \tag{3}$$

# SU(4)? single-particle transition?

- The situation is similar to what is expected from the SU(4) symmetry (no spin or isospin dependent forces).

Review

Overview of neutron–proton pairing

S. Frauendorf<sup>a</sup>, A.O. Macchiavelli<sup>b,\*</sup>

<sup>a</sup> *Department of Physics, University Notre Dame, Notre Dame, IN 46556, United States*

<sup>b</sup> *Nuclear Science Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, United States*

Very recently, Fujita et al. [171] carried out a detailed study of GT excitations for mass number  $A = 42, 46, 50,$  and  $54$  using the  $(^3\text{He}, t)$  reaction at the RCNP Facility in Osaka. Of particular interest to us, are the results observed for the charge exchange reaction from the  $g_s$  of  $^{42}\text{Ca}$  to  $^{42}\text{Sc}$ . The GT strength for this case appears to be concentrated in the lowest  $1^+$  state at  $0.611$  MeV which the authors interpret as a restoration of the SU(4) symmetry in the form of a low-lying collective GT phonon. Shell model calculations with the Kuo–Brown interaction seem to account for the data rather well. With only two valence particles outside closed shells, the direct implication of this observation on the existence of an isoscalar condensate is not clear and shell model indicators do not signal such a condensate. The interpretation of this  $1^+$  state as an isoscalar phonon, seems at variance with the large  $B(M1, 1^+ \rightarrow 0^+)$  which is well described by a  $[\nu f_{7/2} - \pi f_{7/2}]^{1^+}$  configuration [158] and other properties to be discussed in Sections 7 and 8. Moreover, low-lying single-particle levels in  $^{41}\text{Ca}$  and  $^{41}\text{Sc}$  are consistent with  $jj$ - rather than  $LS$ -coupling. One cannot but notice in Fig. 48 that in the SU(4) limit, the single- $l$  model predicts very small values of the total  $B(GT)$ .

- SU(4) is strongly broken by the existence of spin-orbit splitting.
- Single-particle structure?

# From the simple single-particle picture

- Concentration in a single state cannot be accounted for by a simple shell-model argument.

B(GT) distribution with pure configurations

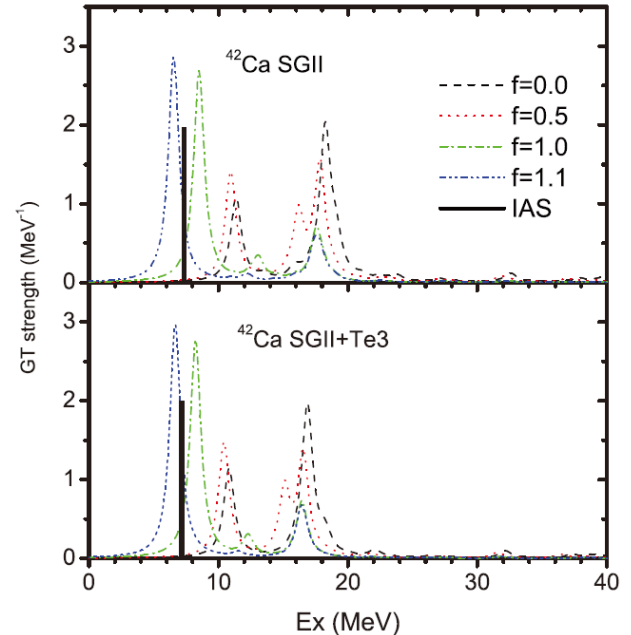

Experimental strength

# Essential role of configuration mixing

- RPA calculation
  - Isoscalar pairing is essential.
- Coherence in the GT transition is also obtained by shell-model calc.
- Why is collectivity created?

C. L. Bai et al., Phys. Rev. C 90, 054335 (2014).

# Two-particle vs. two-hole configurations

- A question by someone (sorry, I do not remember who raised)
  - What about two hole systems?

two-particle:  ${}^6\text{He} \rightarrow {}^6\text{Li}$

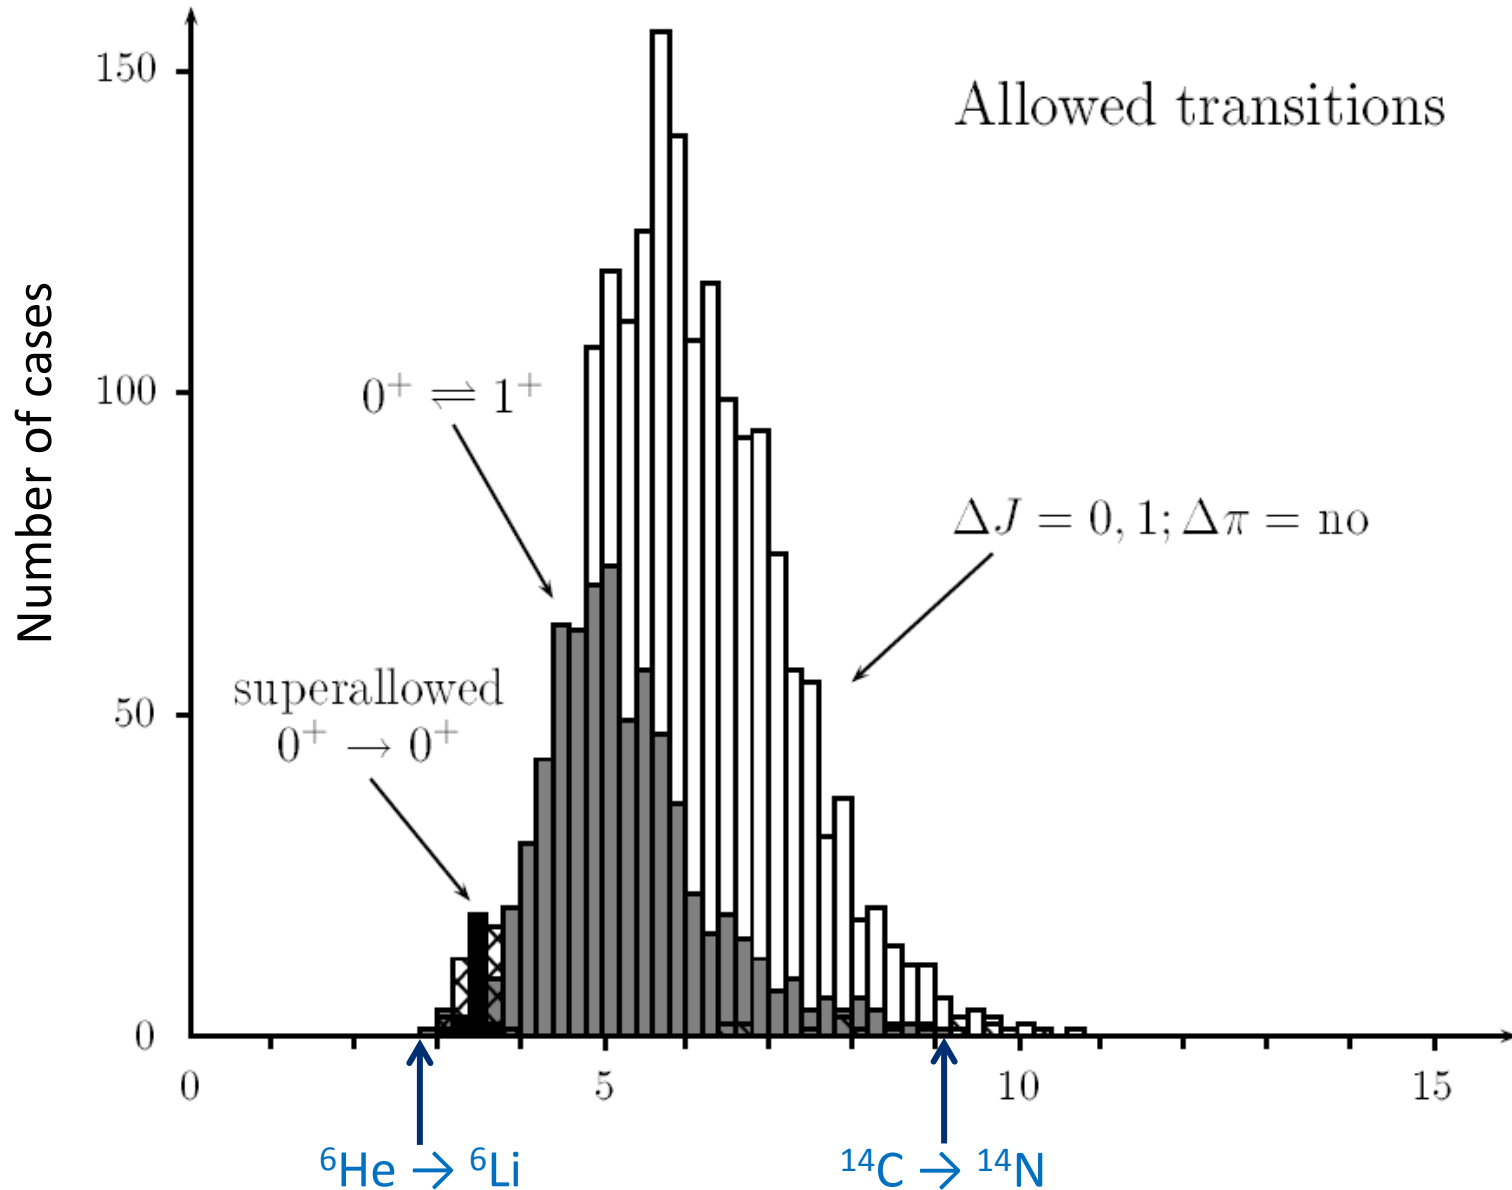

two hole:  ${}^{14}\text{C} \rightarrow {}^{14}\text{N}$

B(GT)	Two-particle			Two-hole	
	<i>p</i>	<i>sd</i>	<i>pf</i>	<i>p</i>	<i>sd</i>
	A=6	A=18	A=42	A=14	A=38
$1^+_1$	4.7	3.1	2.2	$3.5 \times 10^{-6}$	0.060
$1^+_2$		0.13	0.10	2.8	1.5

# Distribution of known $\log ft$

# Questions

- Why does the “low-energy super GT state” appear for two-particle configurations?
- Why is the corresponding  $B(\text{GT})$  values for two-hole configurations very small?
- What does those properties tell us about isovector and isoscalar pairing properties, since correlated two nucleons form a “Cooper pair”?

# Unified treatment of $p$ - $p$ and $h$ - $h$ systems

- The following two descriptions are identical

- Particle Hamiltonian

$$H = \sum_{i\uparrow} \varepsilon_{i\uparrow} a_{i\uparrow}^\dagger a_{i\uparrow} + 1/4 \sum_{i,j,k,l\uparrow} v_{ij;kl} a_{i\uparrow}^\dagger a_{j\uparrow}^\dagger a_{l\uparrow} a_{k\uparrow}$$

- Hole Hamiltonian

$$H = \sum_{i\uparrow} \varepsilon_{i\uparrow} b_{i\uparrow}^\dagger b_{i\uparrow} + 1/4 \sum_{i,j,k,l\uparrow} v_{ij;kl} b_{i\uparrow}^\dagger b_{j\uparrow}^\dagger b_{l\uparrow} b_{k\uparrow}$$

when  $v_{ij;kl} = v_{\downarrow ij;kl}$  and  $\varepsilon_{i\uparrow} = E(i\uparrow - 1)$  are satisfied.

Two-body matrix elements are the same, but the single-particle energies are in the reversed order for the hole-hole Hamiltonian.

# GT strength in $2p$ and $2h$ conf.: $p$ -shell case

- As shown in the last slide, both the  ${}^6\text{He} \rightarrow {}^6\text{Li}$  ( $2p$ ) and  ${}^{14}\text{C} \rightarrow {}^{14}\text{N}$  ( $2h$ ) decays can be described as **two-nucleon systems with the same two-body matrix elements**.
- The only difference between them is the single-particle splitting  $\Delta\varepsilon_{\downarrow p} = \varepsilon(p_{\downarrow 1/2}) - \varepsilon(p_{\downarrow 3/2})$ :
  - For the particle case:  $\Delta\varepsilon_{\downarrow p} = 0.1$  MeV
  - For the hole case:  $\Delta\varepsilon_{\downarrow p} = -6.3$  MeV

} Taken from the Cohen-Kurath's CKII interaction
- It is interesting to plot the Gamow-Teller matrix element  $M(GT) = \langle J_{\downarrow f} | \sigma t \uparrow - | J_{\downarrow i} \rangle$  as a function of  $\Delta\varepsilon_{\downarrow p}$  for given two-body interactions in order to see the dependence on the single-particle energies.

# (1) Cohen-Kurath's CKII interaction

- One of the most popular empirical interactions for the  $p$  shell.
  - 15 two-body matrix elements are deduced by fitting energy levels of  $A=8-16$  nuclei.

## (2) Pairing interaction

- Isoscalar- and isovector-pairing interactions are defined as

$$V_{IV}^{\text{pair}} = G_{IV} \sum_{\mu} P_{\mu}^{\dagger} P_{\mu}$$

$$V_{IS}^{\text{pair}} = G_{IS} \sum_{\mu} D_{\mu}^{\dagger} D_{\mu}$$

where  $P_{\mu}^{\dagger} = \frac{1}{\sqrt{2}} \sum_{nl} (-1)^l \sqrt{2l+1} [a_{nl}^{\dagger} \times a_{nl}^{\dagger}]_{\mu}$

$M_L = 0, M_S = 0, M_T = \mu, L = 0, S = 0, T = 1$  and

$D_{\mu}^{\dagger} = \frac{1}{\sqrt{2}} \sum_{nl} (-1)^l \sqrt{2l+1} [a_{nl}^{\dagger} \times a_{nl}^{\dagger}]_{\mu}$ ,  
 $M_L = 0, M_S = \mu, M_T = 0, L = 0, S = 1, T = 0$ .

- Isovector-pair creation operator  $P_{\mu}^{\dagger}$  and isoscalar-pair creation operators  $D_{\mu}^{\dagger}$  are symmetric in terms of  $S$  and  $T$ .

# $M(\text{GT})$ with the pairing interaction

- Strengths of  $G^{\text{IS}}$  and  $G^{\text{IV}}$  are determined so as to reproduce the mean square  $(J, T)=(1, 0)$  and  $(0, 1)$  matrix elements of CKII.

- $M(\text{GT})$ : Enhanced for small  $\Delta\varepsilon \downarrow p$  and no vanishing for  $\Delta\varepsilon \downarrow p < 0$ .
  - Larger than single-particle limits on the both sides

# Coherence of the GT matrix element

- When two-nucleon wave functions are decomposed into basis states as  $|0 \downarrow k \uparrow + \rangle = \sum ab \uparrow \downarrow \alpha \downarrow ab \uparrow \downarrow V(k) |ab J=0 T=1 \rangle$  and  $|1 \downarrow k \uparrow + \rangle = \sum ab \uparrow \downarrow \alpha \downarrow ab \uparrow \downarrow S(k) |ab J=1 T=0 \rangle$ , the Gamow-Teller matrix element is written as

$$M(GT; 1 \downarrow k \uparrow +) = \sum abcd \uparrow \downarrow m \downarrow abcd (1 \downarrow k \uparrow +)$$

where  $m \downarrow abcd (1 \downarrow k \uparrow +) = \alpha \downarrow ab \uparrow \downarrow S \uparrow^*(k) \alpha \downarrow cd \uparrow \downarrow V(1) ab J=1 T=0 | \sigma t \uparrow - | cd J=0 T=1 .$

- Signs of  $m \downarrow abcd (1 \downarrow k \uparrow +)$** 
  - Constructive or destructive interference—essential for determining large or small B(GT)

# Signs of $m \downarrow abcd (1 \downarrow k \uparrow + )$ : CKII

$$m \downarrow abcd (1 \downarrow k \uparrow + ) = \alpha \downarrow ab \uparrow \downarrow S \uparrow * (k) \alpha \downarrow cd \uparrow \downarrow V (1) ab J=1 T=0 | \sigma t \uparrow - | cd J=0 T=1 .$$

$$\Delta \varepsilon \downarrow p = 5 \text{ MeV}$$

$$\Delta \varepsilon \downarrow p = -5 \text{ MeV}$$

- It looks that the pairing interaction always gives a constructive interference, but realistic interactions do not.

# Theorem for the signs of $m \downarrow abcd (1 \downarrow k \uparrow +)$

When the  $(J, T) = (0, 1)$  and  $(1, 0)$  two-body matrix elements are given by the isovector- and isoscalar-pairing interactions with negative  $G^{\text{IV}}$  and  $G^{\text{IS}}$ , respectively, **all the signs of** in two-nucleon systems **are the same** for *any valence shell* (including multi- $j$  shell) and for *any single-particle splitting*.

$$H^{\uparrow \text{pair}} = \sum_{i \uparrow} \epsilon_{li} a_{li} \downarrow \uparrow + V^{\uparrow \text{pair}}$$

$$V^{\uparrow \text{pair}} = G^{\text{IV}} \sum_{\mu \uparrow} P_{\downarrow \mu \uparrow} P_{\downarrow \mu} + G^{\text{IS}} \sum_{\mu \uparrow} D_{\downarrow \mu \uparrow} D_{\downarrow \mu}$$

$$m \downarrow abcd (1 \downarrow k \uparrow +) = \alpha \downarrow ab \uparrow S \uparrow * (k) \alpha \downarrow cd \uparrow V (1) ab J=1 T=0 | \sigma t \uparrow - | cd J=0 T=1 \geq 0$$

# Proof of the theorem (1)

- Write down  $j$ - $j$  coupled two-body matrix elements:

$$\langle ab J=0 T=1 | V | \text{pair} \rangle \langle cd J=0 T=1 \rangle = G \langle \uparrow \uparrow | V | \chi \downarrow ab \uparrow \uparrow \rangle \langle \downarrow \downarrow | V | \chi \downarrow cd \uparrow \uparrow \rangle$$

$$\langle ab J=1 T=0 | V | \text{pair} \rangle \langle cd J=1 T=0 \rangle = G \langle \uparrow \uparrow | S | \chi \downarrow ab \uparrow \uparrow \rangle \langle \downarrow \downarrow | S | \chi \downarrow cd \uparrow \uparrow \rangle$$

with

$$\langle \downarrow \downarrow | ab \uparrow \uparrow \rangle = (-1)^{\uparrow l \downarrow a} \sqrt{j \downarrow a + 1/2} \delta \downarrow ab$$

$$\langle \downarrow \downarrow | ab \uparrow \uparrow \rangle = \sqrt{2} / (1 + \delta \downarrow ab) (-1)^{\uparrow j \downarrow a - 1/2} \sqrt{(2j \downarrow a + 1)(2j \downarrow b + 1)}$$

$$\{ \uparrow \downarrow | 1/2 \& j \downarrow a \& l \downarrow a @ j \downarrow b \& 1/2 \& 1 \} \delta \downarrow n \downarrow a n \downarrow b \delta \downarrow l \downarrow a l \downarrow b$$

- One can easily show that the sign of  $\langle \downarrow \downarrow | ab \uparrow \uparrow \rangle$  is  $(-1)^{\uparrow l \downarrow a}$  and that that of  $\langle \downarrow \downarrow | ab \uparrow \uparrow \rangle$  is  $(-1)^{\uparrow j \downarrow b - 1/2}$  by using the exact form of  $\{ \uparrow \downarrow | 1/2 \& j \downarrow a \& l \downarrow a @ j \downarrow b \& 1/2 \& 1 \}$ .
- When the conventions of  $| ab J=0 T=1 \rangle = (-1)^{\uparrow l \downarrow a} | ab J=0 T=1 \rangle$  and  $| ab J=1 T=0 \rangle = (-1)^{\uparrow j \downarrow b - 1/2} | ab J=1 T=0 \rangle$  are taken, **all the two-body matrix elements are non positive.**

## Proof of the theorem (2)

- Matrix element of the Hamiltonian

$$H_{ij} = \delta_{ij} (\epsilon_a(i) + \epsilon_b(i)) + V_{ij}$$

- All the *off-diagonal* matrix elements are non positive when the present phase convention.
- From a version of the Perron-Frobenius theorem, the components of the lowest eigenvector are completely of the same sign.

For a matrix  $[h_{11} \dots h_{1n} \dots h_{n1} \dots h_{nn}]$  with  $h_{ij} \leq 0$  ( $i \neq j$ ), the eigenvector  $v = [\alpha_1 \dots \alpha_n]$  satisfies  $\alpha_i \geq 0$  for any  $i$ .

# Proof of the theorem (3)

- Gamow-Teller matrix elements for two-nucleon configurations

C S c o n v e n t i o n					

p r e s e n t c o n v e n t i o n					

Completely the same sign!

# Proof of the theorem (4)

- We go back to  $M(GT; 1 \downarrow k \uparrow +) = \sum_{abcd} m \downarrow abcd (1 \downarrow k \uparrow +)$  with  $m \downarrow abcd (1 \downarrow k \uparrow +) = \alpha \downarrow ab \uparrow S \uparrow^* (k) \alpha \downarrow cd \uparrow IV (1) ab J=1 T=0 | \sigma t \uparrow - | cd J=0 T=1$ .
- All of  $\alpha \downarrow ab \uparrow S \uparrow^* (1)$ ,  $\alpha \downarrow cd \uparrow IV (1)$ , and  $ab J=1 T=0 | \sigma t \uparrow - | cd J=0 T=1$  have fixed signs when the phase conventions of  $| ab J=0 T=1 \rangle = (-1)^{\uparrow l \downarrow a} | ab J=0 T=1 \rangle$  and  $| ab J=1 T=0 \rangle = (-1)^{\uparrow j \downarrow b} -1/2 | ab J=1 T=0 \rangle$  are taken. Therefore, the signs of  $m \downarrow abcd (1 \downarrow 1 \uparrow +)$  are the same for all possible  $(a, b, c, d)$ .
- This is the origin of the coherence (“low-energy super GT state”) obtained for two-particle configurations.

# (rough) Proof of the Perron-Frobenius theorem

- Consider a real-symmetric matrix with  $H=(h_{ij})$  with  $\forall h_{ij} \leq 0$  ( $i \neq j$ ) and let  $v_1 = (\alpha_1, \dots, \alpha_n)$  be the lowest eigenvector.
- Since  $v_1$  is the lowest eigenvector, there is no vector that satisfies  $v^T H v < v_1^T H v_1$ .
- If  $v_1$  contains positive and negative components, one can generally assume  $\alpha_1 \geq 0, \dots, \alpha_k \geq 0, \alpha_{k+1} < 0, \dots, \alpha_n < 0$ . Let  $v_1'$  be  $(\alpha_1, \dots, \alpha_k, -\alpha_{k+1}, \dots, -\alpha_n)$ .
- Since  $v_1^T H v_1 = \sum_{i,j} \alpha_i h_{ij} \alpha_j$ , one gets  $v_1^T H v_1 - v_1'^T H v_1' = \sum_{i \leq k, j > k} 2 \alpha_i h_{ij} \alpha_j > 0$ . This contradicts that  $v_1$  is the lowest eigenvector.

# Graphical image of the P-F theorem

- Represent an off-diagonal matrix element  $h_{ij}$  as a bond that connects the site  $i$  and  $j$ .
- For each site  $i$ , a positive (negative)  $\alpha_i$  is represented as an upward (downward) arrow.
- The right figure shows favored signs, which are analogous to ferromagnetism and antiferromagnetism.
- The situation of P-F theorem is like parallel spin alignment in ferromagnetism that makes energy stable.

# Going back to physics

- The coherence of GT matrix elements is due to the “alignment” of all the two-nucleon configurations, where alignment stands for that coefficients of basis vectors are of the same sign.
- Since this is independent of single-particle energies, such an “aligned” state must be most stable also for two-hole configurations.
- The actual situation is different. This means that some of the off-diagonal matrix elements in the  $(J,T)=(1,0)$  and/or  $(0,1)$  channels are opposite.

# Realistic (J,T)=(0,1) and (1,0) matrix elements

Some isoscalar matrix elements  
have the opposite sign.

# Pairing vs. realistic interactions: $p$ -shell case

- Same signs for isovector matrix elements.
- Opposite sign for  $p \downarrow 3/2 \rightarrow p \downarrow 1/2$   $V \begin{bmatrix} \square \\ \square \end{bmatrix} p \downarrow 1/2 \rightarrow p \downarrow 1/2$  in the  $(J,T)=(1,0)$  channel. This causes “frustration”, which cannot uniquely determine the signs. The actual signs depend on the diagonal matrix elements.
  - Two-particle config.: coherent due to the dominance of  $v \downarrow 1$  and  $v \downarrow 2$
  - Two-hole config.: non coherent due to dominance of  $v \downarrow 2$  and  $v \downarrow 3$

# Origin of difference in sign

- We consider the matrix elements of the delta interaction as a short-range central interaction.

- The j-j coupled matrix elements are written as

$$\langle abJT | \delta(r) | cdJT \rangle = C \sum_{LS} (L+S+T=\text{odd}) \eta_{ab}(LSJ) \eta_{cd}(LSJ)$$

$$\text{with } \eta_{ab}(LSJ) = \sqrt{1 - (-1)^{S+T} / (1 + \delta_{ab})} \gamma_{LS}(J)(a,b) (-1)^{n_a + n_b} \sqrt{(2l_a + 1)(2l_b + 1)} \left( \begin{matrix} L & l_a & l_b \\ 0 & 0 & 0 \end{matrix} \right)$$

$$\text{and } \gamma_{LS}(J)(a,b) = \sqrt{(2j_a + 1)(2j_b + 1)} (2L + 1)(2S + 1) \left\{ \begin{matrix} l_a & l_b & J \\ 1/2 & 1/2 & L+S \end{matrix} \right\}$$

- $C$  depends on  $(n_a, l_a)$  etc., but we assume a constant  $C$  which is called the surface delta interaction.
- In this case, **the  $L=0$  contributions are exactly the same as the pairing matrix elements.**

# $L=0$ and 2 contributions

- $\langle ab | JTV \uparrow S D I | cd \rangle_{JT} = C \downarrow 0 \sum LS (L+S+T=\text{odd}) \uparrow \eta \downarrow ab (LSJ) \eta \downarrow cd (LSJ)$
- Restrictions
  - $J=L+S$ ;  $S=0$  or  $1$ .
  - $L$  is only even when one considers a single-major shell, since  $\eta \downarrow ab (LSJ) \propto (-1)^L \eta \downarrow a \eta \downarrow b$  (see [1]).
- Possible  $LS$ 
  - Only  $LS=00$  for  $(J,T)=(0,1)$
  - $LS=01$  and  $21$  for  $(J,T)=(1,0)$

One must take the  $LS=21$  term into account when fully evaluating the matrix elements of short-range central forces.

# Cancellation due to $L=2$

- $abJT \uparrow \text{SDI} \downarrow cdJT = C \downarrow 0 \sum LS (L+S+T=\text{odd}) \uparrow \eta \downarrow ab (LSJ) \eta \downarrow cd (LSJ)$

- Exact expression of  $nlab (l, s-1, l-1)$  divided by  $s-(-1)^{l+1} i/h$

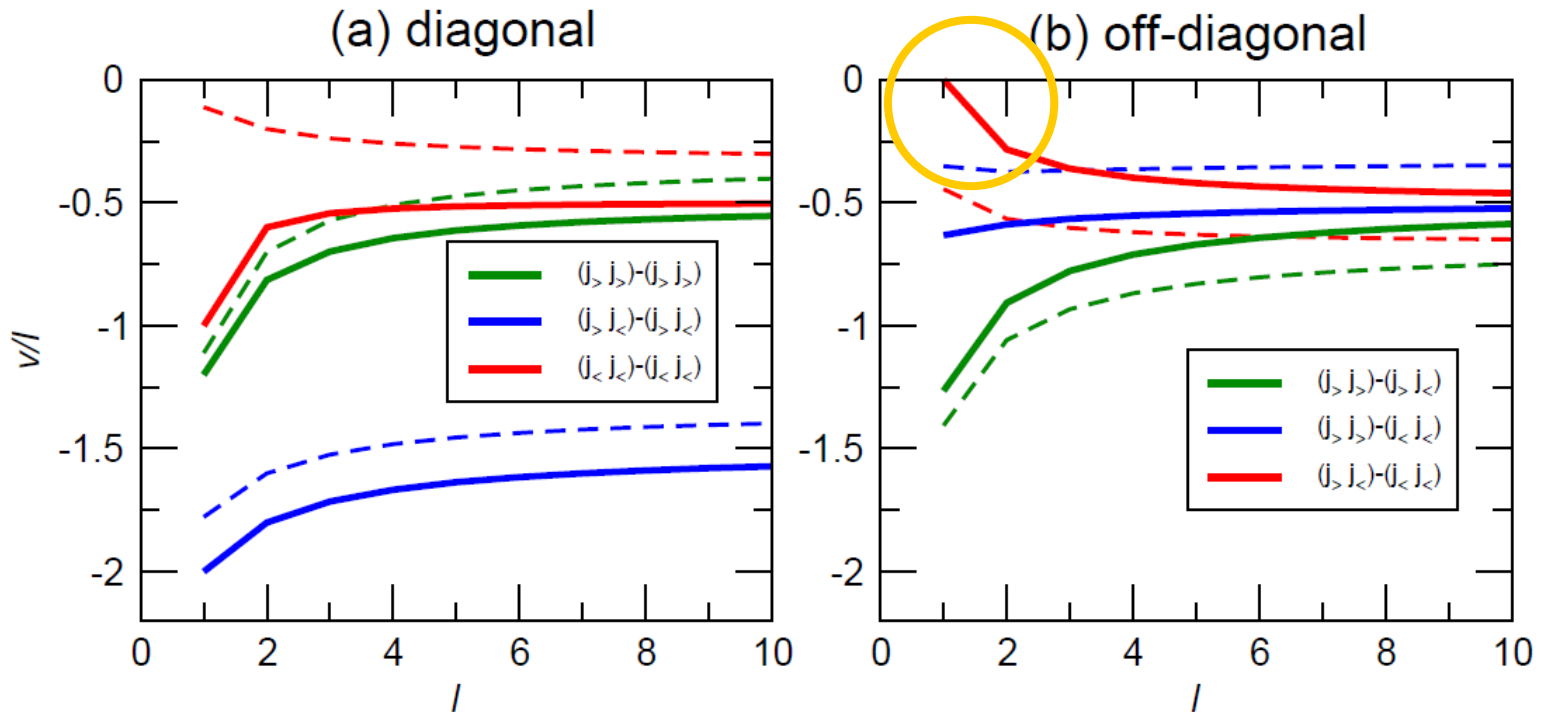

$(a, b)$	$(j_>, j_>)$	$(j_>, j_<)$	$(j_<, j_<)$	$(j_<, j_>)$
$L = 0$	$\sqrt{\frac{(l+1)(2l+3)}{3(2l+1)}}$	$\sqrt{\frac{8l(l+1)}{3(2l+1)}}$	$\sqrt{\frac{l(2l-1)}{3(2l+1)}}$	
$L = 2$	$\sqrt{\frac{2l^2(l+1)}{3(2l+1)(2l+3)}}$	$-\sqrt{\frac{l(l+1)}{3(2l+1)}}$	$\sqrt{\frac{2l(l+1)^2}{3(2l-1)(2l+1)}}$	$-\sqrt{\frac{3(l+1)(l+2)}{2l+3}}$

$$l' = l - 2$$

- Clearly, cancellation due to  $L=2$  occurs for  $j_> j_> V \boxed{A} j_> j_<$  and  $j_< j_< V \boxed{A} j_> j_<$ .

# Quantitative argument

- $ab J=1 T=0 V \uparrow$  SDI  $cd J=1 T=0 / l$  with the convention of  $(-1)^{\uparrow} j \downarrow b - 1/2$   $|ab J=1 T=0 \rangle \downarrow$  Condon-Shortley

- $j \downarrow < j \downarrow < V \boxed{A} j \downarrow > j \downarrow <$  with low- $l$  are strongly cancelled by  $L=2$ .
- Finite-range interactions can make  $j \downarrow < j \downarrow < V \boxed{A} j \downarrow > j \downarrow <$  positive.

# Frustration caused by $\Delta l=2$ mixing

- Matrix elements concerning  $|j\downarrow < j\downarrow > \uparrow\rangle$  with  $l\uparrow = l-2$  (such as  $|d\downarrow 3/2 s\downarrow 1/2 \rangle$ ) does not appear with the  $L=0$  terms, and can be an additional source of frustration.
- The sign of  $h\downarrow 12 h\downarrow 23 h\downarrow 31$  is invariant under phase transformation. When it is positive, the frustration occurs among  $v\downarrow 1, v\downarrow 2$  and  $v\downarrow 3$   $\eta\downarrow ab (L S=1 J=1)/(-1)^{\uparrow j\downarrow b - 1/2}$

$(a, b)$	$(j>, j>)$	$(j>, j<)$	$(j<, j<)$	$(j<, j'>)$
$L = 0$	$\sqrt{\frac{(l+1)(2l+3)}{3(2l+1)}}$	$\sqrt{\frac{8l(l+1)}{3(2l+1)}}$	$\sqrt{\frac{l(2l-1)}{3(2l+1)}}$	
$L = 2$	$\sqrt{\frac{2l^2(l+1)}{3(2l+1)(2l+3)}}$	$-\sqrt{\frac{l(l+1)}{3(2l+1)}}$	$\sqrt{\frac{2l(l+1)^2}{3(2l-1)(2l+1)}}$	$-\sqrt{\frac{3(l+1)(l+2)}{2l+3}}$

# Tensor-force contributions

- Pointed out by Talmi in terms of the origin of long lifetime of  $^{14}\text{C}$ .
- Evaluation with the  $\pi+\rho$  meson exchange tensor force using the  $(-1)^{\uparrow j \downarrow b - 1/2} |ab J=1 T=0\rangle \downarrow$  Condon–Shortley convention

# Pair transfer matrix elements

- It is often discussed that pair transfer probability is a good measure of pairing correlation.
- Isoscalar pair creation and removal probabilities:

$$| \langle J \downarrow f T \downarrow f || D \uparrow \uparrow || J \downarrow i T \downarrow i \rangle |^2 \quad \text{and} \quad | \langle J \downarrow f T \downarrow f || D || J \downarrow i T \downarrow i \rangle |^2$$

	Pair creation on vacuum	Pair removal from closure
$p$	8.1	$5.3 \times 10^{-3}$
$sd$	15.7	1.7

# Possible effects on pair condensate

- On the basis of strong  $T=0$  attractive force, isoscalar pair condensates are expected to occur especially around  $N=Z$  nuclei, similar to well-known isovector pair condensates.
  - $|\Psi\rangle = (A \uparrow \uparrow)^{\uparrow N} |-\rangle$  with the Cooper pair  $A \uparrow \uparrow = \sum_{ab} \lambda_{ab} [a \downarrow i \uparrow \uparrow \times a \downarrow j \uparrow \uparrow] \uparrow J=1 T=0$
- There seems to be no strong evidence for isoscalar pair condensates in the actual nuclei.
- As shown in this talk, the signs of the isoscalar pair are not uniquely determined because of frustration. This is a possible reason why isoscalar pair condensates are not well established.

# Summary

- We have exactly proven that the GT matrix elements in two-nucleon configurations (2p and 2h) are always in phase with the isovector- and isoscalar-pairing interactions, which accounts for “low-energy super GT states”.
- The observed hindrance of the GT matrix elements in two-hole configurations is due to “non coherence” of realistic  $(J,T)=(1,0)$  matrix elements, which cannot give definite signs in “Cooper pairs”.
- Difference in sign between isoscalar-pairing and realistic interactions is predominantly caused by  $L=2$  central forces and tensor forces.
- This effect can prevent correlated proton-neutron pair from forming isoscalar-pair condensates, which are not established in experiment.
