## The 2HDM potential

$$V(\Phi_1, \Phi_2) = m_1^2 \Phi_1^\dagger \Phi_1 + m_2^2 \Phi_2^\dagger \Phi_2 - (m_{12}^2 \Phi_1^\dagger \Phi_2 + \text{h.c.}) + \frac{1}{2} \lambda_1 (\Phi_1^\dagger \Phi_1)^2 + \frac{1}{2} \lambda_2 (\Phi_2^\dagger \Phi_2)^2 \\ + \lambda_3 (\Phi_1^\dagger \Phi_1) (\Phi_2^\dagger \Phi_2) + \lambda_4 (\Phi_1^\dagger \Phi_2) (\Phi_2^\dagger \Phi_1) + \frac{1}{2} \lambda_5 [(\Phi_1^\dagger \Phi_2)^2 + \text{h.c.}]$$

$$\phi_1 \rightarrow \phi_1 \quad \phi_2 \rightarrow -\phi_2$$

**“Normal” vacuum (CP conserving and non charge breaking)**

$$\langle \Phi_1 \rangle_N = \begin{pmatrix} 0 \\ v_1 \end{pmatrix} \quad \langle \Phi_2 \rangle_N = \begin{pmatrix} 0 \\ v_2 \end{pmatrix}$$

**8 + 2 parameters - 2 are fixed by the minimum conditions and one by the W mass  $v^2 = v_1^2 + v_2^2$ . The remaining 7 are**

$$m_h, m_H, m_A, m_{H^\pm}, \tan \beta, \sin \alpha \quad M^2 = \frac{m_{12}^2}{\sin \beta \cos \beta}$$

# The 2HDM Lagrangian

- couplings that involve gauge bosons

$$\sin(\beta - \alpha)$$

- couplings that involve fermions

$$\begin{aligned} \phi_1 &\rightarrow \phi_1 \\ \phi_2 &\rightarrow -\phi_2 \end{aligned}$$

We extend the  $Z_2$  symmetry to the fermions -  
4 independent Yukawa Lagrangians

	I	II	III	IV
up	$\Phi_2$	$\Phi_2$	$\Phi_2$	$\Phi_2$
down	$\Phi_2$	$\Phi_1$	$\Phi_1$	$\Phi_2$
lepton	$\Phi_2$	$\Phi_1$	$\Phi_2$	$\Phi_1$

III = I' = Y = Flipped

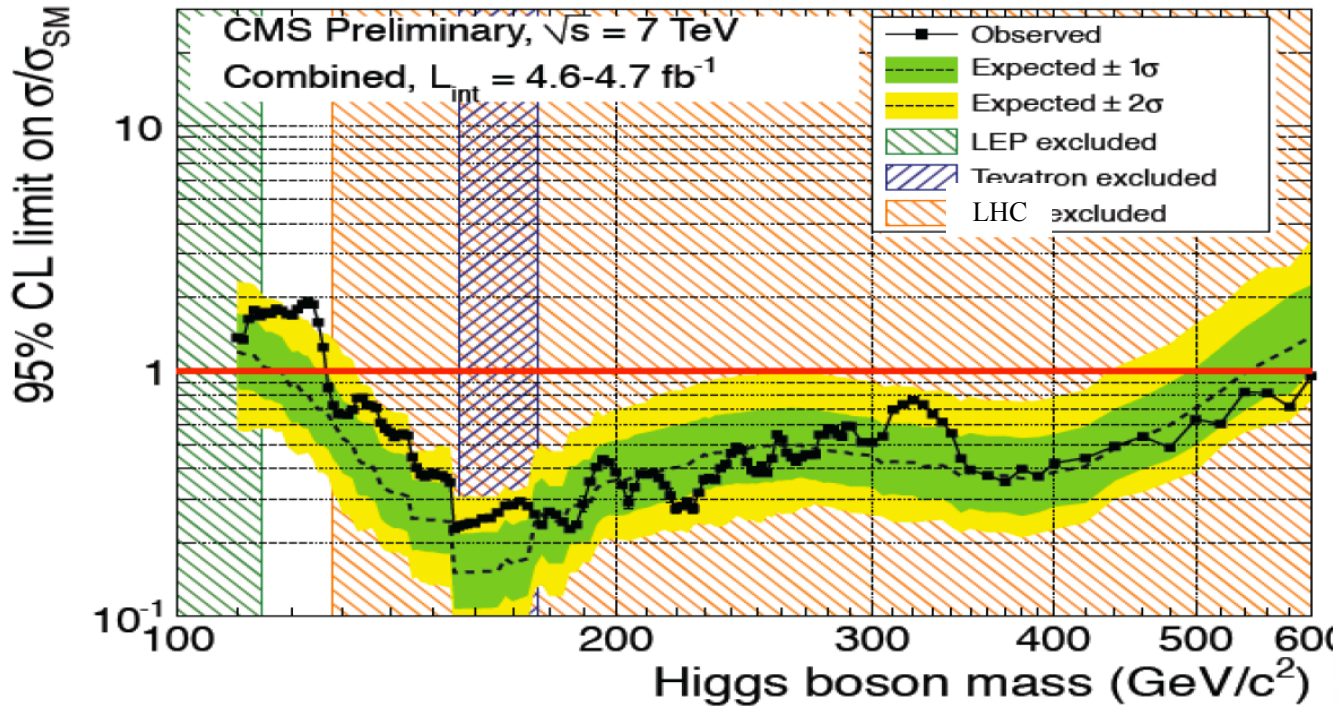

IV = II' = X = Leptonic

4 models with no FCNC at tree-level

	I	II	III	IV
leptons (h)	$\frac{\cos \alpha}{\sin \beta}$	$-\frac{\sin \alpha}{\cos \beta}$	$\frac{\cos \alpha}{\sin \beta}$	$-\frac{\sin \alpha}{\cos \beta}$
down (h)	$\frac{\cos \alpha}{\sin \beta}$	$-\frac{\sin \alpha}{\cos \beta}$	$-\frac{\sin \alpha}{\cos \beta}$	$\frac{\cos \alpha}{\sin \beta}$
up (h)	$\frac{\cos \alpha}{\sin \beta}$	$\frac{\cos \alpha}{\sin \beta}$	$\frac{\cos \alpha}{\sin \beta}$	$\frac{\cos \alpha}{\sin \beta}$
leptons (H)	$\frac{\sin \alpha}{\sin \beta}$	$\frac{\cos \alpha}{\cos \beta}$	$\frac{\sin \alpha}{\sin \beta}$	$\frac{\cos \alpha}{\cos \beta}$

LEE significance is 1.9 standard deviations

# Higgs results LHC@7TeV

- What do we “know”?

$$\frac{\sigma^{2HDM}(pp \rightarrow h) BR^{2HDM}(h \rightarrow \gamma\gamma)}{\sigma^{SM}(pp \rightarrow h) BR^{SM}(h \rightarrow \gamma\gamma)} \approx 1$$

regarding production and decay  
to  $\gamma\gamma$  ( $VV$ )

$$\frac{\sigma^{2HDM}(pp \rightarrow h) BR^{2HDM}(h \rightarrow VV)}{\sigma^{SM}(pp \rightarrow h) BR^{SM}(h \rightarrow VV)} \approx 1$$

2HDM is similar to the SM

- What will data on new channels tell us?

$$\frac{\sigma^{2HDM}(pp \rightarrow h) BR^{2HDM}(h \rightarrow \bar{b}b)}{\sigma^{SM}(pp \rightarrow h) BR^{SM}(h \rightarrow \bar{b}b)}$$

how important are  
future searches for 2HDM?

$$\frac{\sigma^{2HDM}(pp \rightarrow h) BR^{2HDM}(h \rightarrow \tau^+\tau^-)}{\sigma^{SM}(pp \rightarrow h) BR^{SM}(h \rightarrow \tau^+\tau^-)}$$

# The Constraints

## Experimental

### • INDIRECT BOUNDS

All models

$$Z \rightarrow b\bar{b} \quad B_q \bar{B}_q$$

$$\tan\beta > 1$$

Used in all  
calculations  
presented.

$$\rho = \frac{M_W^2}{M_Z^2 c_W^2} = 1$$

$$\left\{ \begin{array}{l} m_A = m_{H^\pm} \\ \sin(\beta - \alpha) = 1 \Rightarrow m_{H^\pm} = m_H \\ \sin(\beta - \alpha) = 0 \Rightarrow m_{H^\pm} = m_h \end{array} \right.$$

$$|\delta\rho| \lesssim 10^{-3}$$

Compact spectrum

## Experimental

### • INDIRECT BOUNDS B factories

$$B \rightarrow X_s \gamma$$

**Models II and Y**  $X_i Y_i = 1$

**Models I and X**  $X_i Y_i = 1/\tan^2 \beta$

$$\mathcal{L}_Y^\pm = (2\sqrt{2}G_F)^{1/2} \sum_{i=2}^n (X_i \bar{U}_L V M_D D_R + Y_i \bar{U}_R M_U V D_L + Z_i \bar{N}_L M_E E_R) H_i^\pm + \text{h.c.}$$

$$\text{BR}(b \rightarrow s \gamma) = C |\eta_2 + G_W(x_t) + (|Y|^2/3)G_W(y_t) + (XY^*)G_H(y_t)|^2,$$

**Models II and Y**

$$m_{H^\pm} \gtrsim 300 \text{ GeV}$$

**Best available bound on the charged Higgs mass**

**Models I and X**

$$\tan \beta > 1$$

$$m_{H^\pm} = 100 \text{ GeV}$$

# h or H?

- All results will be presented in the  $(\tan\beta; \sin\alpha)$  plane.
  - We started with 7 parameters.
- One of the CP-even Higgs mass is “known” (125 GeV).
- The other CP-even Higgs mass is either irrelevant or benchmarks will be discussed.
- $m_{H^\pm} = m_A = 600 \text{ GeV}$  (relevant only h to  $\gamma\gamma$  due to charged Higgs loop).
  - $M = m_{H^\pm} = m_A$  or  $M = 0$ .

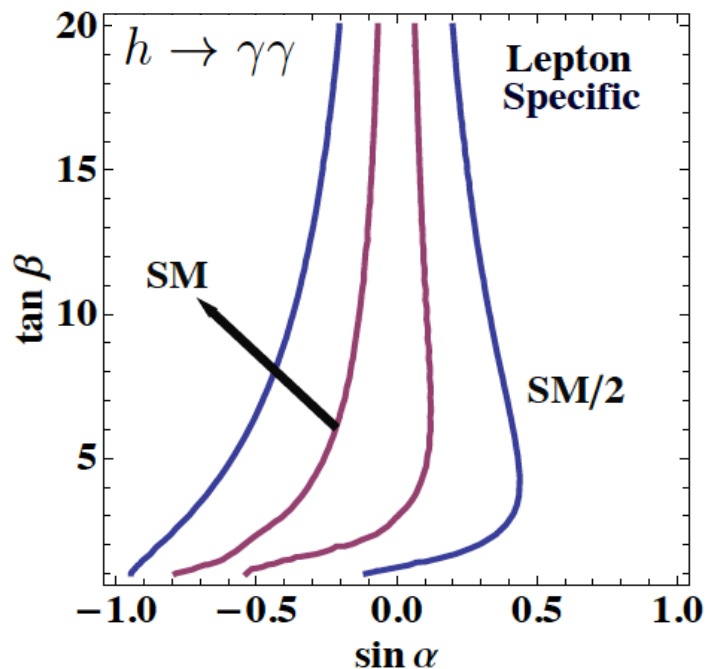

## Is it the light CP-even (h)?

$$\frac{\sigma^{2HDM}(pp \rightarrow h) BR^{2HDM}(h \rightarrow \gamma\gamma)}{\sigma^{SM}(pp \rightarrow h) BR^{SM}(h \rightarrow \gamma\gamma)}$$

In the quark sector sector I = LS and the cross section ratio is just  $\cos^2 \alpha / \sin^2 \beta$ .

In Model I the ratio never reaches  $2*SM$ .

When  $\sin \alpha \approx \pm 1$  the Higgs becomes fermiophobic and therefore it is not produced in gluon fusion.

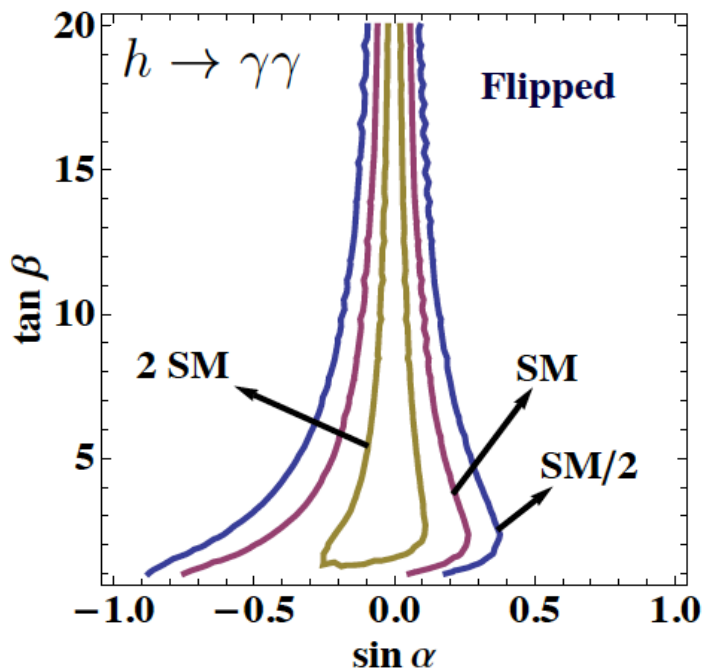

In LS as the total width grows with  $\tan \beta$  (due to  $h \rightarrow \tau\tau$ ) the allowed region to fit the Higgs shrinks. Again no  $2*SM$ .

## Is it the light CP-even?

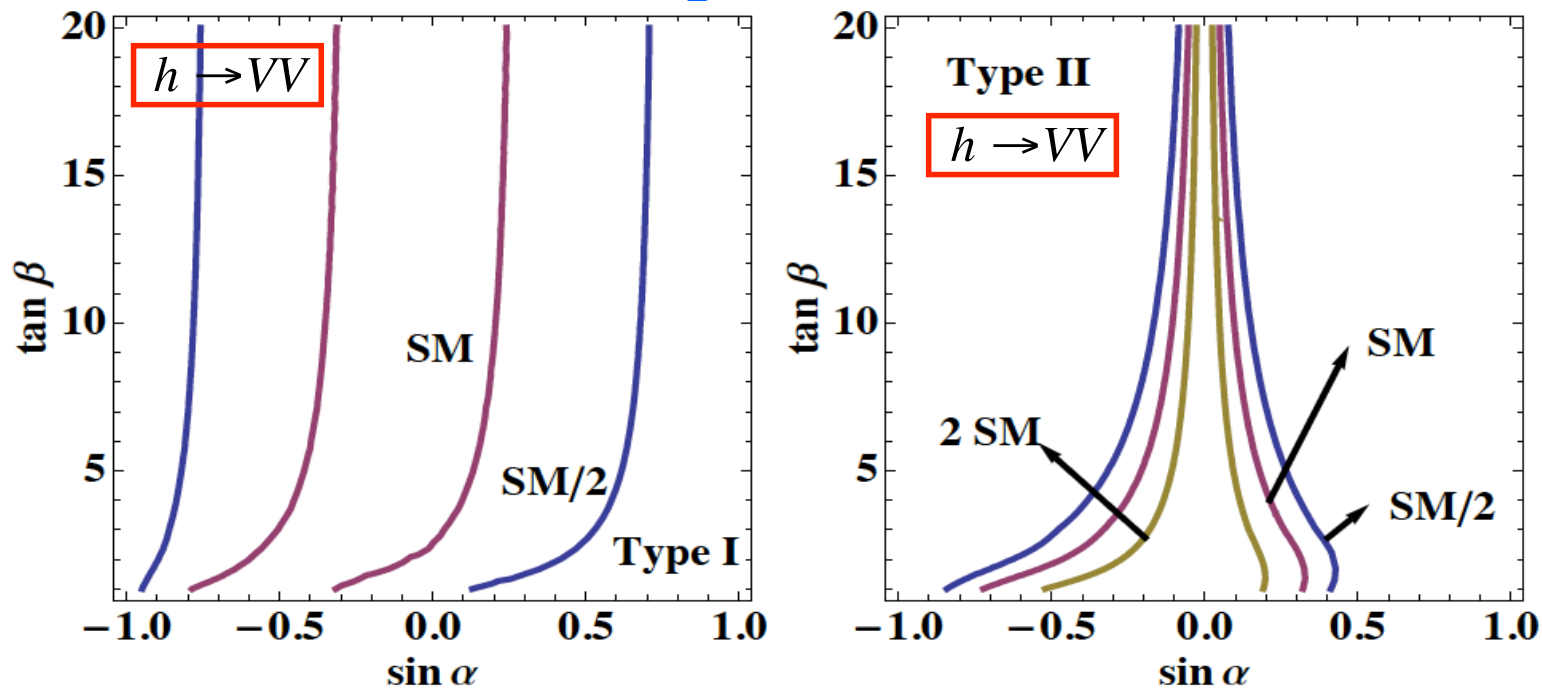

Again, in the quark sector sector II = F  
But now the ratio is not just a factor.

The contributions of the b-quark become important and even dominant for large  $\tan \beta$  for both production and decay. This completely changes the picture: we can be above but also below the SM prediction.

For these models, the region of parameter space where we get a number of events close to SM, is more likely to be in the region of small  $\sin \alpha$  especially for large  $\tan \beta$ .

## Is it the light CP-even?

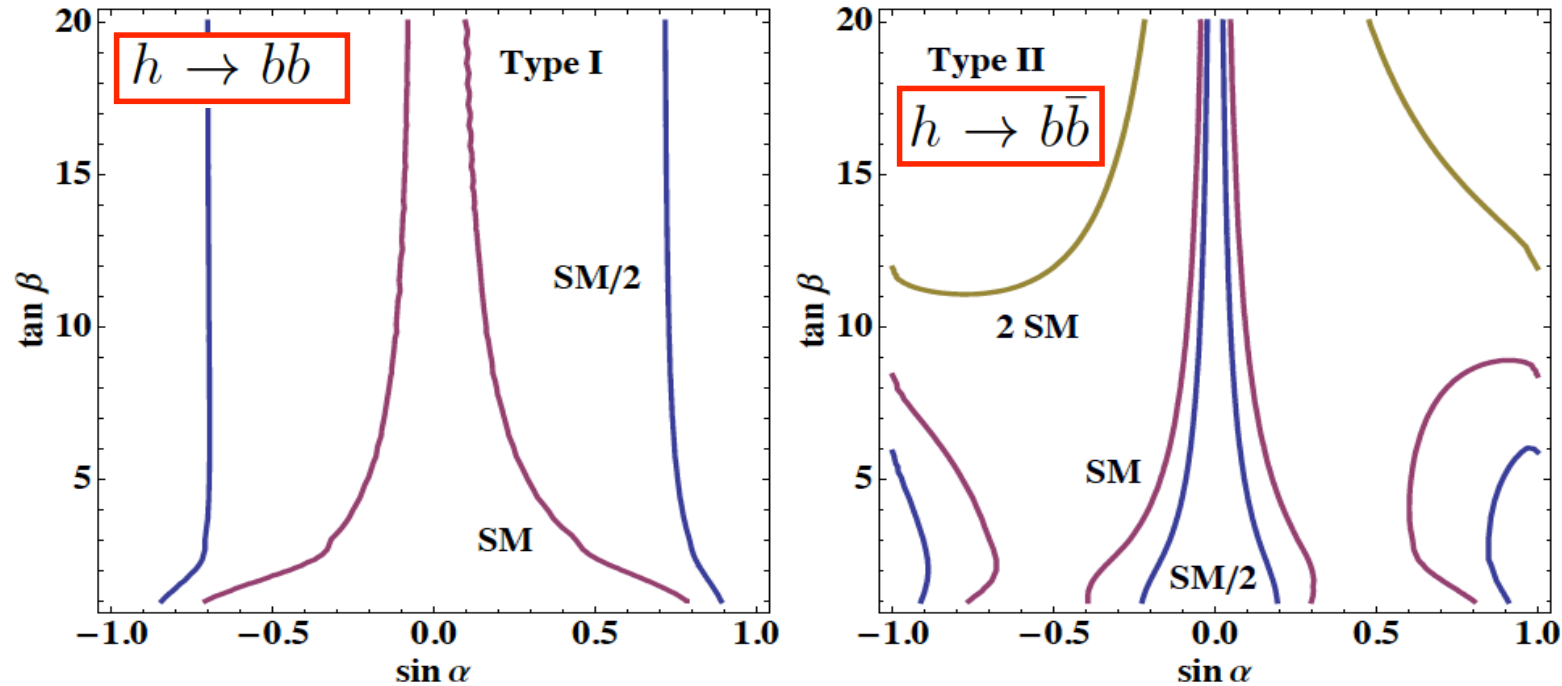

A few events have also been detected in  $h \rightarrow WW + ZZ$ .

Does this information help improving the constraint in the  $(\tan \beta; \sin \alpha)$  plane?

Model I and LS - the ratio is never much bigger than 1. Information about this decay is unlikely to prove useful in further constraining the parameter space; but a substantial enhancement would imply physics beyond the 2HDM.

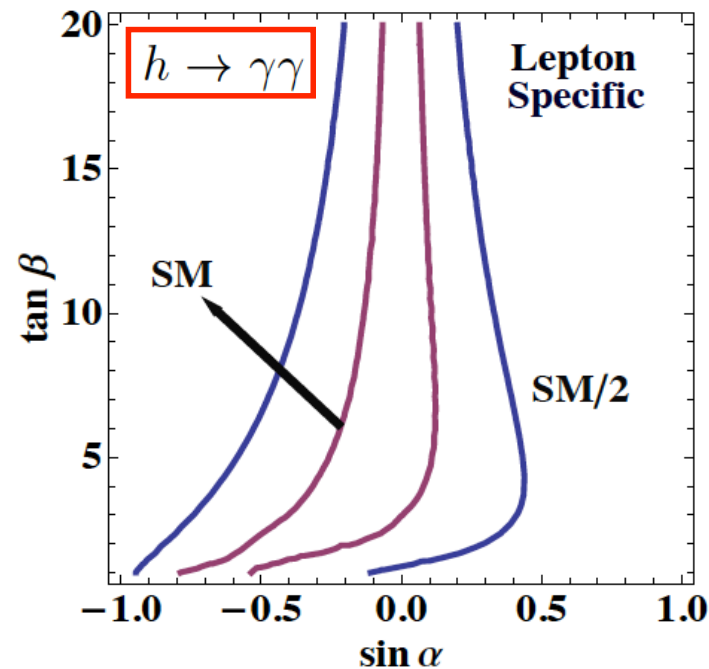

Model II and F - irrelevant unless huge enhancement happens...

## Is it the light CP-even?

We have also analysed the decay  $h \rightarrow b\bar{b}$ . For the type I model one sees relatively little variation over much of parameter space. For the type II model, there is a much larger variation. However, if one restricts the parameter space to that allowed by the signal, then the variation is fairly small. The same happens in the LS and F models.

## Is it the light CP-even?

For the LS model the  $\tau\tau$  channel gives dramatically different constraints in the  $(\tan\beta; \sin\alpha)$  plane.

If one can limit the

rate for  $h$  to  $\tau\tau$  down to less than twice the SM rate, then the parameter space will be much more severely restricted than implied by other processes.

## Is it the light CP-even?

- Data is consistent with the Higgs detected being the lightest CP-even scalar of a 2HDM in all four models.
- With the data to be collected this year and even combining all searches (channels) we will not be able to identify or exclude models unless:
  - a) Number of gamma events is much above/below SM
  - b) Number of WW/ZZ events is much above/below SM.
  - c) Indication of the LS model would be an enhancement in  $h$  to  $\tau\tau$

## Is it the heavy CP-even?

- Hints for a 125 GeV state decaying into two photons. In the context of 2HDMs:  $h$ ,  $H$  or  $A$ ?
- We now focus on the heavier CP-even scalar,  $H$ .
- The lightest scalar  $h$  should have, thus far, evaded detection.
- The combined requirements on  $H$  and  $h$  place stringent limits on the parameter space. We will consider two qualitatively distinct cases.
- Case 1:  $m_h = 105$  GeV and  $m_H = 125$  GeV, thus precluding the decay  $H$  to  $hh$ .
- Case 2:  $m_h = 50$  GeV and  $m_H = 125$  GeV, implying that  $H$  to  $hh$  is kinematically allowed.

## Is it the heavy CP-even?

**LEP constraints**

- LEP experiments searched for associated production of a light Higgs up to masses around 115 GeV.
- In 2HDMs, rates with  $hVV$  couplings ( $V = Z; W$ ) are suppressed by  $\sin^2(\beta-\alpha)$ , which the LEP data constrains to lie below 0.2 for  $m_h = 105$  GeV.
- This implies a very stringent constraint on the  $(\sin\alpha; \tan\beta)$  plane, shown for  $m_h = 105$  GeV (light yellow shaded areas).
- For  $m_h = 50$  GeV,  $\sin^2(\beta-\alpha) < 0.04$  leads to even smaller allowed regions, shown in as dark red areas.

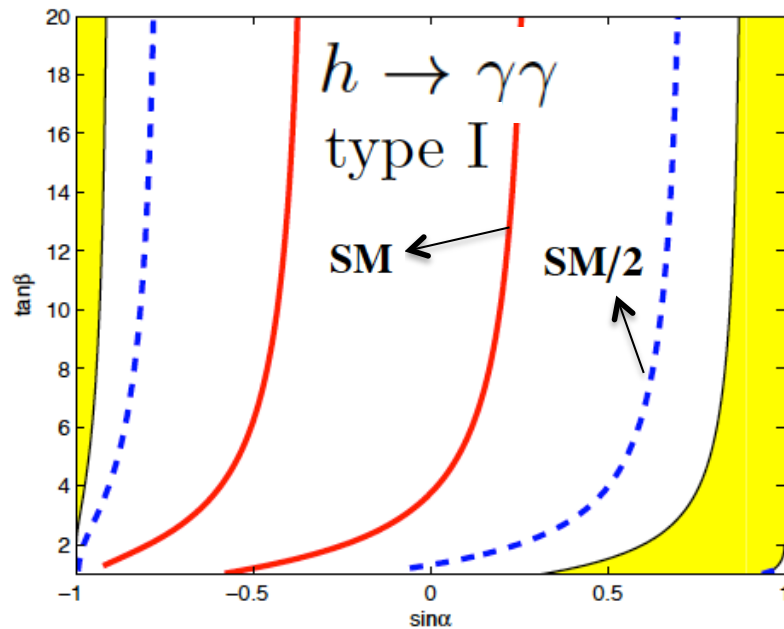

The LEP constraints forces  $\sin\alpha$  to be close to  $\pm 1$ , with a severe impact on the observability of the lightest Higgs.

## Is it the heavy CP-even?

- Case 1:  $m_h = 105 \text{ GeV}$ ,  $m_H = 125 \text{ GeV}$ .

- The decay of the heavy Higgs has to lie very close to its SM value. SM/2 is excluded. This is consistent with its detectability in this channel at the LHC.

- For the light Higgs all values above SM/2 are excluded and therefore for this scenario the lightest Higgs decay into two photons will not be seen at LHC in the near future.

## Is it the heavy CP-even?

- An interesting situation for type I 2HDM arises in the decays into  $bb$ .
- We find that  $H$  can decay into  $bb$ , with  $SM$  or with  $SM/2$  ratios, in a small region close to  $(\sin\alpha; \tan\beta) = (0.7; 2)$ .
- This is the same region in which  $h$  to  $bb$  could have a rate close to the  $SM$  one. The same conclusions hold for  $H$  to  $\tau\tau$  and  $h$  to  $\tau\tau$ .
- This raises the interesting possibility that the decays into  $bb$  and  $\tau\tau$  could be sensitive to both the heavy and the light Higgs scalars, while only  $H$  can be seen in the  $\gamma\gamma$  and  $VV$  channel at the LHC.

## Is it the heavy CP-even?

- In model type II and Flipped both the decays to two photons and to VV are similar to type I - the only difference is that values of  $2 \cdot \text{SM}$  or larger, can be reached. Again  $h$  is undetectable in the decays to gauge bosons.

- But the situation may improve with respect to the type I model, concerning  $bb$ . We see that both  $H$  to  $bb$  and  $h$  to  $bb$  could occur at rates twice the SM rate, for  $\sin\alpha > 0.8$  and  $\tan\beta > 13$ .

- Similar behavior is seen in  $\tau\tau$ .

## Is it the heavy CP-even?

- Next we consider the LS model. As in the type I model,  $h$  to two photons is unobservably small, while  $H$  may be detected.

- Unlike model I, we see that the decays of both  $h$  and  $H$  into  $\tau\tau$  could be substantially larger than in the SM. Also, they prefer to be close to  $\sin \alpha = \pm 1$ .

- The decays into  $bb$  have features similar to those for model I. In particular, detection of  $H$  to  $bb$  at SM rates is possible for large  $\sin \alpha$  and any value for  $\tan \beta$ , but simultaneous detection of  $h$  to  $bb$  around SM rates is only possible for low values of  $\tan \beta$ .

## Is it the heavy CP-even?

- Case 2:  $m_h = 50 \text{ GeV}$  and  $m_H = 125 \text{ GeV}$ , implying that  $H$  to  $hh$  is kinematically allowed.
- When  $H$  to  $hh$  is opened, all other branching ratios are much suppressed and, in particular,  $H$  could not even be seen in the  $\gamma\gamma$  channel. This violates our working hypothesis that current LHC hints correspond indeed to  $H$  to  $\gamma\gamma$ . As a result, we are interested in regions where  $\lambda_{Hhh}$  is close to zero.

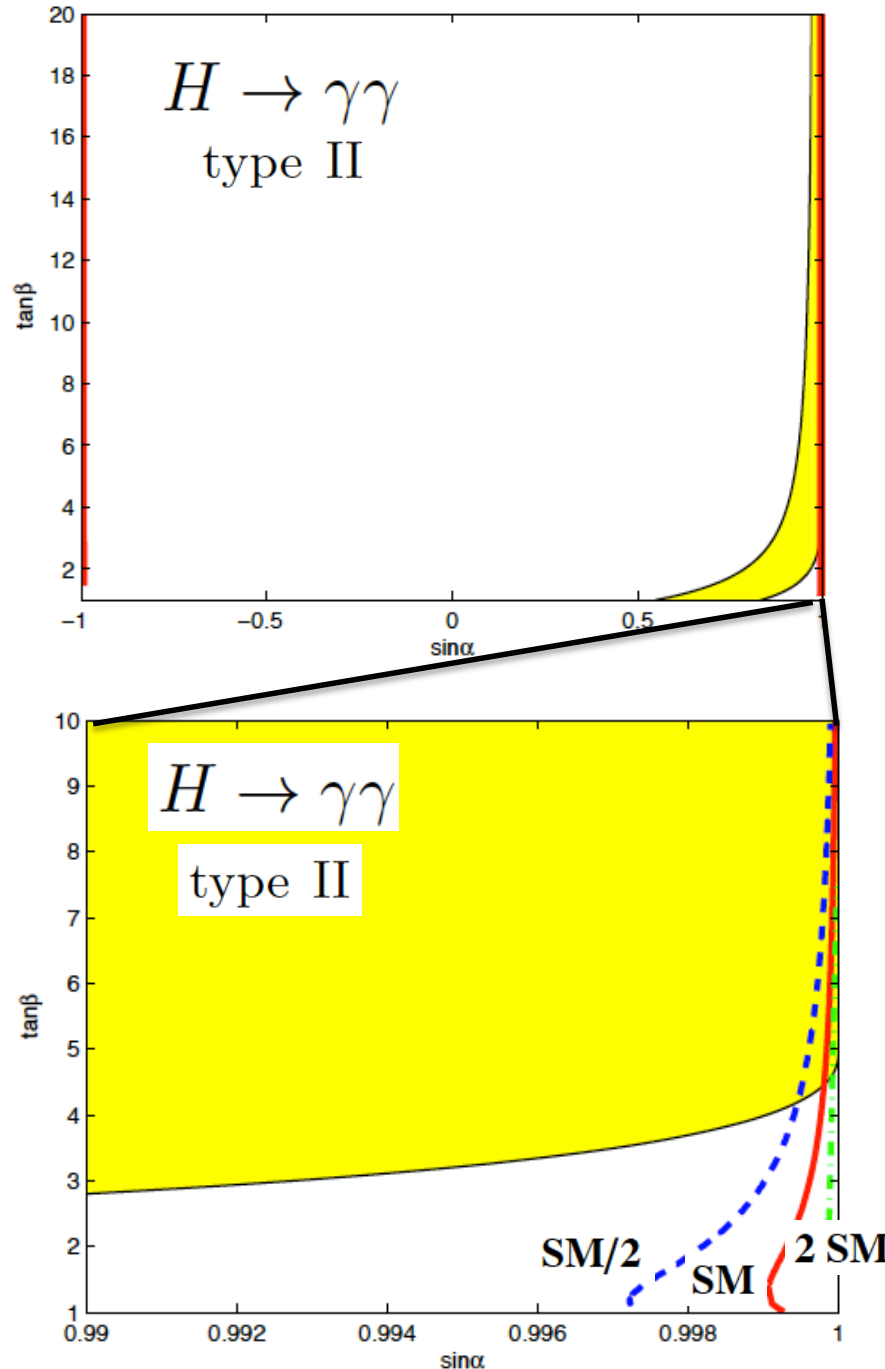

$$\lambda_{Hhh} \propto \frac{\cos(\beta - \alpha)}{\sin(2\beta)} (m_H^2 + 2m_h^2) \sin(2\alpha) \left[ 1 - x \left( \frac{3}{\sin(2\beta)} - \frac{1}{\sin(2\alpha)} \right) \right]$$

a) Exact Z2:  $m_{12} = 0$ .

b) Softly broken Z2:  $m_{12} \neq 0$ .

$$x = \frac{2m_{12}^2}{m_H^2 + 2m_h^2}$$

## Is it the heavy CP-even?

- If  $m_{12} = 0$   $\lambda_{Hhh}$  is close to zero when  $\sin\alpha = \pm 1$  or 0 but only  $\sin\alpha = \pm 1$  are consistent with the LEP bounds (shown in yellow).

- Only close to  $\sin\alpha = \pm 1$  H may be visible in H to  $\Upsilon\Upsilon$  or in any other channel other than H to hh. This a necessary but not a sufficient condition.

- Similar conclusions for the remaining models.

- The results are approximately the same for H to VV .

- Regarding bb and  $\tau\tau$ : H might be seen in both decays for type I; it might be seen in bb but not in  $\tau\tau$  for LS; it might be seen in  $\tau\tau$  but not in bb for the Flipped; and it will not be seen in either for the type II model.

## Is it the heavy CP-even?

- If  $m_{12} = 0$ , the  $\sin\alpha = \pm 1$  constraint also has a very strong impact on the detectability of the light scalar h.
- To avoid the LEP bound, h is close to gaugephobic. Thus, it cannot be seen in VV, regardless of the specific 2HDM considered.
- We have checked that h to  $\gamma\gamma$  and h to bb is undetectable, while h to  $\tau\tau$  is only detectable in the LS model.
- Notice that, in the scenario  $m_H = 125$  GeV,  $m_h = 50$  GeV, and  $m_{12} = 0$ , the LS model has a very interesting prediction: H may be seen in  $\gamma\gamma$ , VV, and bb at rates around the SM value, but it will not show up in  $\tau\tau$ , while h exhibits exactly the opposite features.

## Is it the heavy CP-even?

$$\frac{2m_{12}^2}{m_H^2 + 2m_h^2} = \frac{\sin(2\alpha)\sin(2\beta)}{3\sin(2\alpha) - \sin(2\beta)}$$

- Lines in the  $(\sin\alpha; \tan\beta)$  plane where  $\lambda_{Hhh}$  vanishes. A judicious choice of  $m_{12}$  guarantees that  $H$  to  $\gamma\gamma$  is not swamped by  $H$  to  $hh$ .

- If  $m_{12} \neq 0$  we might have  $H$  to  $\gamma\gamma$  at levels consistent with LHC hints in regions away from  $\sin\alpha = \pm 1$ .

- This is shown as a scatter plot drawn for the type II model (similar for all other models) and for random choices of  $m_{12}$ . One can now cover almost the entire LEP allowed region.

- In this case, the phenomenology is very similar to the  $m_h = 105$  GeV case.

## Is it the heavy CP-even?

- Case 1:  $m_h = 105 \text{ GeV}$ ,  $m_H = 125 \text{ GeV}$ .

Model /Process	$H \rightarrow \gamma\gamma$	$H \rightarrow VV$	$H \rightarrow \bar{b}b$	$H \rightarrow \tau^+\tau^-$

Type I	No	No	No	No
Type II	No	No	No	No
Flipped	No	No	No	No
LS	No	No	No	Yes

## Bounds from $\tau\tau$

- The experimental searches on  $h$  to  $\tau\tau$  already allow us to set bounds on the 2HDM parameter space

- Type II and LS are the most constrained models due to the large cross section and branching ratio into  $\tau\tau$ . Note that in LS, the allowed regions close to  $\sin\alpha = \pm 1$  are not compatible with  $h$  being detected in  $\gamma\gamma$  at rates close to the SM rates.

- No bounds on models I and Flipped because either cross section or branching ratio into  $\tau\tau$  is too small.

# Conclusions

- In a CP-conserving 2HDM with a softly broken  $Z_2$  symmetry, both  $h$  and  $H$  scalars are consistent with the LHC results presented so far.
- More luminosity will probably tell us if the number of  $\gamma\gamma$  and  $VV$  events is consistent with the SM predictions. A large difference in either  $\gamma\gamma$  or  $VV$  may be explained by a 2HDM.
- Bounds derived from experimental searches on  $h$  to  $\tau\tau$  and  $h$  to  $bb$  may help clarify which types of 2HDM's are allowed (or at least constrain the parameter space).

# Workshop on Multi-Higgs Models

28-31 August 2012

Lisbon - Portugal

This Workshop brings together those interested in the theory and phenomenology of Multi-Higgs models. The program is designed to include talks given by some of the leading experts in the field, and also ample time for discussions and collaboration between researchers. A particular emphasis will be placed on identifying those features of the models which are testable at the LHC.

For registration and/or to propose a talk, send an email to:

# Theoretical

Remaining parameters are fixed by the theoretical constraints - tree-level vacuum stability (potential is bounded from below at tree-level) and perturbative unitarity.

## Is it the heavy CP-even?

- In all four models, decays  $h$  to  $\gamma\gamma$ ,  $WW$  and  $ZZ$  will be unobservable.
- $H$  to  $hh$  is kinematically inaccessible. Type I: decays of  $h$  and  $H$  into  $bb$  and  $\tau\tau$  can both be observed at a rate similar to SM. Type II and Flipped: decays can both occur at rates twice that of the SM. In LS one can have a huge enhancement in the  $H$  to  $\tau\tau$  and  $h$  to  $\tau\tau$  rates.
- $H$  to  $hh$  is kinematically allowed, and will generally be large.

If  $m_{12} = 0$ ,  $\sin\alpha = \pm 1$  -  $h$  to  $\gamma\gamma$ ,  $VV$  and  $bb$  is undetectable, while  $h$  to  $\tau\tau$  is only detectable in the LS model.

If  $m_{12} \neq 0$ , the region of parameter-space in which the  $\lambda_{Hhh}$  coupling is suppressed is substantially expanded, and can cover most of the LEP-allowed region (similar results as for case I).
